

# Modelling data networks – introduction

Richard G. Clegg (richard@richardclegg.org)—

Available online at <http://www.richardclegg.org/lectures> accompanying printed notes provide full bibliography.

(Prepared using  $\text{\LaTeX}$  and beamer.)

# Difficulties in modelling the Internet

- See “Difficulties in simulating the internet” Floyd & Paxson 2001.
- The internet is big (and growing).
- The internet is heterogenous to a large degree.
- No central maps exist of the internet.
- The internet is not always easy to measure.
- The internet is rapidly changing.
- It is extremely important to be able to model the internet.

The internet cannot possibly be modelled, yet we must model the internet. How can this be resolved?

# Aim of these of lectures

Learn about basic mathematics necessary to model the internet

## Stochastic processes

Modelling how things arrive on a network (in particular the Poisson process).

## Markov chains

A useful way of modelling the state of networks and necessary for queuing theory.

## Queu(e)ing theory

The mathematics of how things queue – packets in routers, processes in a CPU...

# Steps to modelling

- How you model the network depends critically on the problem you are solving.
- What are you trying to show with your model?
- Metrics: what are we trying to measure?
  - ① Throughput?
  - ② Goodput?
  - ③ System efficiency?
- Validation: what real data can be used to check the model?
- Sensitivity: what happens if your assumptions change?
  - ① What if the demand on the system is slightly different?
  - ② What happens if delays and bandwidths are changed?
  - ③ What happens if users stay longer or download more?

# Important questions for modelling

- ① How much of the network do we model?
  - Whole internet (then we can't even model every computer – every AS?)
  - A few typical nodes?
  - A sub net?
  - A single queue and buffer?
- ② What level of modelling is appropriate?
  - Mathematical – solution “instant” (or quick)
  - Detailed simulation
  - Combined approach (equations abstract away some details with approximations)
- ③ How far down the network stack need we go?

# Model example one – peer-to-peer network

## Modelling Task

Test the possible improvements expected if we try a locality aware peer selection policy on a global bittorrent network.

What must our model include?

- 1 The distribution of nodes (peers) on the overlay network (not the whole network).
- 2 The delay and throughput between these peers (must depend on distance to some extent).
- 3 How users arrive and depart.
- 4 What users choose to download.

Note that this might already be a vast modelling task with hundreds of thousands or even millions of nodes.

# Approach to model one – peer-to-peer network

- Research existing P2P models, do any fit? Don't reinvent the wheel.
- Real data: What real-life measurements exist to validate against?
- If we are modelling a new peer selection we must be sure our model covers existing peer selection well.
- Metrics: what must we measure in our model?
  - 1 Overall throughput/goodput?
  - 2 Distribution of time taken for peers to make their download?
  - 3 Total resources used in system?
- Validation: Instrumented P2P clients exist – how do they compare to our simulation.
- Sensitivity: Different distribution of users? Different delays and throughputs?

## Model example two – Buffer overflow model

### Modelling task

Given a router with a buffer, how does the buffer size in packets affect the probability of packet loss?

What must our model include?

- 1 A model of the incoming packets to the buffer.
- 2 The rate at which packets leave the buffer.
- 3 Possibly distribution of packet lengths in bytes.
- 4 Possibly the feedback (TCP) between packet loss and arrival rate.

## Approach to model two – Buffer overflow model

- Research: what is known about the statistics of internet traffic?
- What is the distribution of inter-arrival times and packet lengths?
- Metrics:
  - ① Packet loss.
  - ② Packet delay.
- Sensitivity: What if we change the following parameters:
  - ① The total arrival rate.
  - ② The bandwidth of the outgoing link.
- Validation: Real traffic traces (CAIDA has a collection).

# Model example three – TCP protocol model

## Modelling Task

Test a possible improvement to the TCP model which aims to improve fairness and throughput when flows share a link.

What must our model include?

- ① Individual packet model (existing TCP protocol well modelled).
- ② A reasonable estimate of how long each connection lasts and the rate at which new connections.
- ③ A model of the probability of round trip time for the parts of the connection not on the link being modelled.
- ④ A model of the probability of packet loss on the link (due to buffer overflow?)

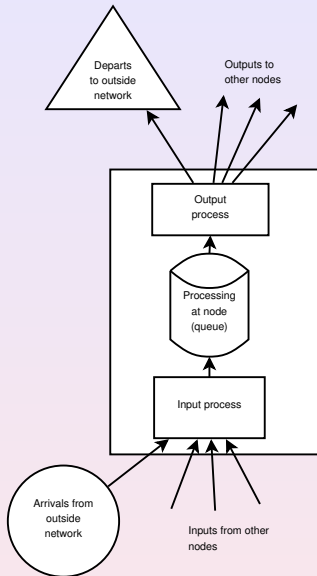

## Approach to model three – TCP protocol model

- Can existing network models help (ns-3/mininet could be an obvious choice)?
- What if the existing protocol shares a link with flows using the old protocol.
- Metrics:
  - ① Throughput and goodput.
  - ② Fairness between flows.
- Sensitivity, what if we change these parameters:
  - ① Number of flows using existing and new protocol.
  - ② Bandwidth of link.
  - ③ Round trip time of flows.
  - ④ Probability of packet loss.
- Validation: Does our model agree with real measurements?

## Other things to model

- Of course depending on the nature of your modelling, there may well be other aspects of the network to be modelled.
- Some examples might be:
  - ① Reliability of nodes and links.
  - ② Possible hostile attacks to the network.
- In all cases, an important starting point is to find out what research already exists in the area.
- Are any real-life data sets available which could inform your modelling? Could you gather such data?

# The basics of a network model

# The basics of a network model

A network model could be viewed as these components.

## Arrival process

A statistical process describing how objects (packets) arrive in the network – statistical process modelling.

## Queueing process

A model which describes how objects (packets) are processed by a network node – queueing theory.

## Topology

A “network topology” – the wiring diagram which shows how these things connect together.

# Check your understanding

What are the concepts being described here?

- The response of a model to changes in its input data.
- Checking a model's performance against real world data.
- The process describing how and when new objects arrive in a network.

# Check your understanding

What are the concepts being described here?

- The response of a model to changes in its input data.  
**Sensitivity**
- Checking a model's performance against real world data.  
**Validation**
- The process describing how and when new objects arrive in a network. **Arrival process**

# Rest of lectures

The rest of these lectures will, therefore, cover:

- Statistical processes – in particular the Poisson process.
- Markov chains – a useful modelling tool in themselves and a prerequisite for...
- Queuing theory – the mathematical study of how things join and leave queues.

Finally a short lecture will cover:

- A summary of basic research in the internet.
- A brief demo of a well-known network modelling tool ns-3 and a virtual network controller.
